# ABSTRACT

Arctic grayling *Thymallus arcticus* were captured by pulsed direct-current electrofishing in two sections of the lower 152 kilometers of the Chena River in 1988. Stock status of Chena River Arctic grayling was described by population abundance, age composition, size composition, growth, recruitment, and survival estimates. Estimated population abundance in the lower 72 kilometers of the Chena River (Lower Chena section) was 7,760 Arctic grayling greater than 149 millimeter fork length; and was 14,444 Arctic grayling greater than 149 millimeter fork length in the upper 80 kilometers of the Chena River (Upper Chena section). Age 5 Arctic grayling were strongly represented in both sections of the Chena River, while size composition varied among river sections. Growth of Chena River Arctic grayling was successfully modelled with the von Bertalanffy growth equation. Annual recruitment between 1986 and 1987 was 2,526 Arctic grayling and annual survival during this period was 43.9 percent. Annual recruitment increased to 3,373 Arctic grayling between 1987 and 1988, with an increase in annual survival to 57.1 percent. All stock status indicators were estimated with high precision, although estimated annual survival between 1986 and 1987 was imprecise. Imprecision of the survival estimate was due to imprecision of the 1986 abundance estimate.

KEY WORDS: Arctic grayling, *Thymallus arcticus*, electrofishing, population abundance, age composition, size composition, Relative Stock Density, growth, recruitment, survival rate, Chena River.

<sup>1</sup> Taken from Mills 1979-1988.

<sup>2</sup> Lower Chena River is from the mouth upstream to 40 km Chena Hot Springs Road (Mills (1987)).

<sup>3</sup> Upper Chena River is the Chena River and tributaries accessed from the Chena Hot Springs Road beyond 40 km on the road (Mills 1987).

<sup>4</sup> Angler-days and harvest are computed for the Chena River and Badger Slough.

<sup>5</sup> Averages are for 1979 through 1987 only.

### Harvest of Arctic grayling

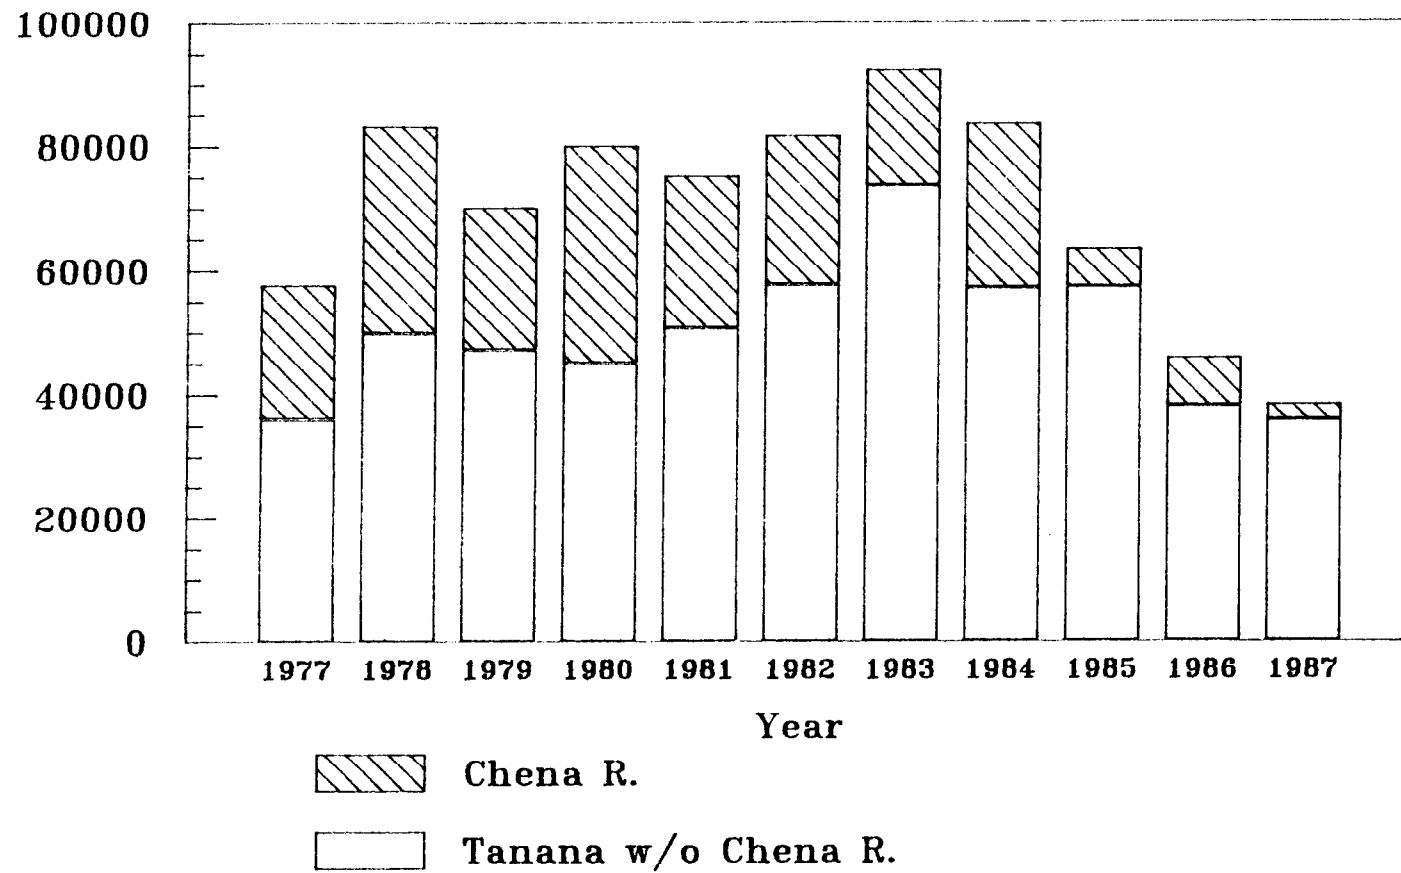

Figure 1. Annual harvests of Arctic grayling in the Chena River and in the entire Tanana drainage excluding the Chena River, 1977-1987 (taken from Mills 1979-1988).

## INTRODUCTION

### Background

The Chena River supports one of the largest Arctic grayling fisheries in North America. For the nine year period from 1979 to 1987, the Chena River produced an average annual sport harvest of 18,736 Arctic grayling in 26,386 man-days of angling effort (Table 1). As recently as 1984, annual harvests had exceeded 20,000 fish and 30,000 man-days of effort and harvests of Arctic grayling from the Chena River comprised a substantial portion of total Arctic grayling harvests in the Tanana River drainage (Figure 1). However, the status of this fishery has changed since 1984. Recreational harvest of Arctic grayling has declined to historic low levels. Harvest decreased 76% from 1984 to 1985, although angling effort had decreased only 39% (Table 1). Angling effort returned to an average level in 1986, but harvest remained below 10,000 fish. Concomitant with the declining recreational fishery was the decline in Arctic grayling population abundance. Stock assessment projects during 1986 (Clark and Ridder 1987a) and 1987 (Clark and Ridder 1988) documented a decline in population abundance of 49% between these two years. Poor recruitment was the probable cause for a decline in abundance (Holmes 1984; Holmes et al. 1986).

During winter of 1986, fishery managers were scheduled to present stock status data (Clark 1986) on the Chena River fishery to the Alaska Board of Fisheries. The Board of Fisheries meeting adjourned before the data could be presented. In spring of 1987, increased concern for the health of the Chena River stock prompted fishery managers to process emergency regulations to reduce harvest. These emergency regulations were:

- 1) closure of the fishery until the first Saturday in June;
- 2) a 12 inch (305 mm) minimum length limit; and,
- 3) restriction of terminal gear to unbaited artificial lures.

These emergency regulations were made permanent regulations in the summer of 1987. During the winter of 1987, fishery managers presented stock status and regulatory concerns to the Alaska Board of Fisheries (Clark 1987). The emergency regulations imposed in spring of 1987 were adopted and amended. The new permanent regulations were:

- 1) catch-and-release fishing from 1 April to the first Saturday in June;
- 2) a 12 inch (305 mm) minimum length limit from the first Saturday in June until 31 March;
- 3) restriction of terminal gear to unbaited artificial lures only throughout the Chena River, and bait fishing allowed downstream of the Moose Creek Dam with hooks having a gap larger than 0.75 inch (19 mm);

## METHODS

### Sampling Gear and Techniques

All sampling was performed with a pulsed-DC (direct current) electrofishing system mounted on a 6.1 m long river boat as previously described by Lorenz (1984). Input voltage (240 VAC) was provided by a 3,500 W single-phase gas powered generator (Homelite Model HG3500). A variable voltage pulsator (Coffelt Manufacturing Model VVP-15) was used to generate output current. Anodes were constructed of 9.5 mm diameter and 1.5 m long twisted steel cable. Four anodes were attached to the front of a 3 m long "T-boom" attached to a platform at the bow of the river boat. The aluminum hull of the river boat was used as the cathode.

Output voltages during sampling varied from 200 to 300 VDC. Amperage varied from 2.0 to 4.0 A. Duty cycle and pulse rate were held constant at 40% and 80 Hz, respectively. These operating characteristics were presumed to minimally affect Arctic grayling survival during mark-recapture experiments. Holmes and McBride (in prep.) found that mortality and injury rates of Arctic grayling were lower for pulsed-DC electroshock than for their control gears (hook-and-line and seine).

Sampling was conducted along the banks of the Chena River. The electrofishing boat was directed downstream along each bank, collecting all Arctic grayling seen, when possible. Captured Arctic grayling were held in an aerated holding tub to reduce capture related stress. The selected areas of the Chena River were sampled no more than once per day to prevent changes in capture probabilities of marked fish (Cross and Stott 1975). Each Arctic grayling was measured to the nearest 1 millimeter FL. A sample of scales was taken from the preferred zone<sup>1</sup> of each newly captured Arctic grayling. Arctic grayling greater than 149 mm FL were marked with individually numbered Floy FD-68 internal anchor tags inserted at the base of the dorsal fin. The tip of the left pelvic fin was removed to identify marked fish in case the numbered tag was shed. If any captured Arctic grayling exhibited signs of injury or imminent mortality, they were immediately sacrificed. Sacrificed fish were examined for sex and maturity, and the sagittal otoliths removed for comparison with age determined by scales.

### Population Abundance

The abundance of Arctic grayling greater than 149 mm FL was estimated by mark-recapture techniques in the lower 152 km of the mainstem Chena River. Two sections of the Chena River were delineated for separate estimation experiments. Delineation of the Chena River was necessary because Tack (1980) and Clark and Ridder (1989) found increasing density of Arctic grayling with increasing distance upstream. Based on differences in population density from downstream to upstream areas of the Chena River, the lower 152 km of the Chena River is divided into Lower and Upper sections for estimating abundance and

<sup>1</sup> The preferred zone for Arctic grayling is an area approximately six scale rows above the lateral line just posterior to the insertion of the dorsal fin.

- 4) catch-and-release fishing year around from river kilometer 140.8 downstream to river kilometer 123.2; and,
- 5) reduce the possession limit from 10 to 5 fish (Tanana drainage-wide regulation).

The regulations adopted by the Board of Fisheries in winter of 1987 were the first changes in Arctic grayling management since 1975, when the daily bag limit was decreased from 10 to 5 fish. Evaluation of the effects of new regulations on the Arctic grayling stock and recreational anglers was begun in 1987.

#### Stock Assessment Goals and Objectives

Much of what is known about Arctic grayling population dynamics comes from research conducted in the Tanana drainage and particularly the Chena River. Stock status of Arctic grayling in the Chena River is measured on an annual basis, primarily during late June and all of July. Population abundance, age composition, size composition, growth, recruitment, and survival are estimated each year to determine the health of the stock. The long-term goals of stock assessment on the Chena River are to:

- 1) accurately and precisely describe the stock status of Chena River Arctic grayling on an annual basis;
- 2) use stock status data in models that predict the consequences of regulatory actions; and,
- 3) provide fishery managers with stock status data and model results so that informed management decisions can be made.

As stock status data are collected over a series of years, predictive models can be created to determine the effects of sport fishing on the Arctic grayling stock. The success of modelling efforts is dependent on the accuracy and precision of stock status data. If the first two goals are successful, the third goal is essentially fulfilled. Therefore, attainment of the first goal is essential to the management process and future health of the stock.

As part of attaining the first stock assessment goal, the objectives of the 1988 research efforts were to:

- 1) estimate the absolute abundance of Arctic grayling greater than 149 mm fork length (FL) in the lower 152 km of the Chena River;
- 2) estimate the age composition of Arctic grayling in the lower 152 km of the Chena River; and,
- 3) estimate Relative Stock Density (RSD) of Arctic grayling in the lower 152 km of the Chena River.

age composition. Downstream from the Moose Creek Dam complex to the mouth of the Chena River was designated the Lower Chena River (72 km long; Figure 2). Upstream from the dam to the second bridge on the Chena Hot Springs Road (kilometer 63.2) was designated the Upper Chena River (80 km long; Figure 3). Population abundance estimates pertain only to these two sections of the Chena River, excluding Badger Slough, the Little Chena River, and the South Fork of the Chena River.

#### Lower Chena River:

Population abundance in the Lower Chena River was estimated by expansion of abundance estimates in four 3.2 km-long sample areas (Clark and Ridder 1987b, 1988), utilizing a stratified design (Cochran 1977). Expansion of these estimates was accomplished by first subdividing the Lower Chena River into two subsections. Each subsection was chosen on the basis of river morphology and hydrologic characteristics that might influence Arctic grayling density. The first subsection (Lower Chena A) encompassed the lower 40 km of river. The second subsection encompassed 32 km below the Moose Creek Dam complex. Two of the four 3.2-km sample areas were randomly chosen in each of the subsections (2 strata, 2 samples per stratum). Sampling took place between 26 June and 8 July.

Multiple-sample population estimates were performed in each of the 3.2-km sample areas. Two of the areas were sampled once each day during a five day time span. Capture histories from each sample area were used as input to program CAPTURE (White et al. 1982). Program CAPTURE was used to perform a rigorous examination of assumptions necessary to multiple-sample abundance estimators. The assumptions necessary for accurate estimation of abundance in a closed population are (from Seber 1982):

- 1) the population is closed (no change in the number of Arctic grayling in the population during the estimation experiment);
- 2) all Arctic grayling have the same probability of capture in the first sample or in the second sample, or marked and unmarked Arctic grayling mix randomly between the first and second samples;
- 3) marking of Arctic grayling does not affect their probability of capture in the second sample;
- 4) Arctic grayling do not lose their mark between sampling events; and,
- 5) all marked Arctic grayling are reported when recovered in the second sample.

Assumption 1 could not be tested directly, but was implicitly assumed because of the short duration of the experiment (five days). Assumption 2 was tested with statistical procedures within program CAPTURE and with a Kolmogorov-Smirnov (Conover 1980) statistical test. Assumption 3 was tested for validity by program CAPTURE. Assumption 4 was assured of validity by double marking of Arctic grayling. Assumption 5 was assumed to be valid by rigorous examination of all Arctic grayling captured and by double marking.

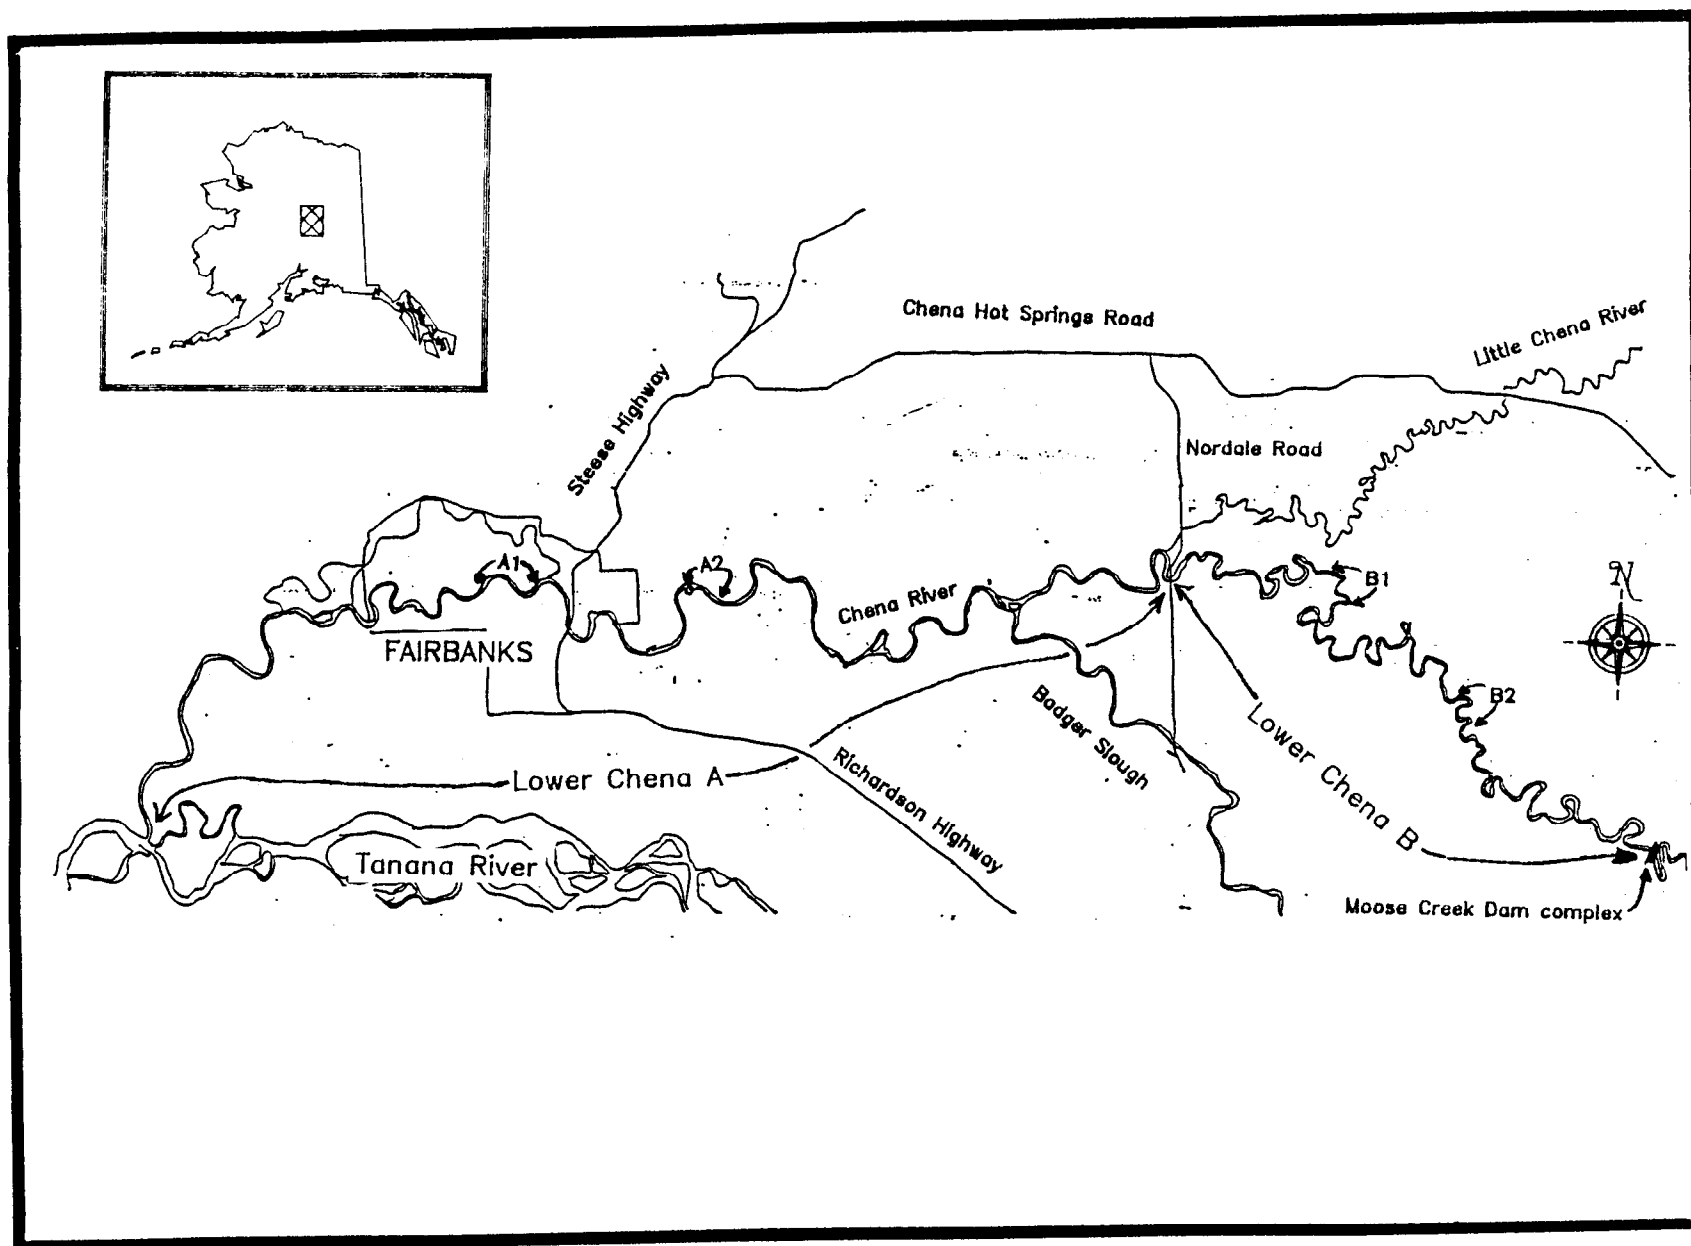

Figure 2. The Chena River below the Moose Creek Dam complex (Lower Chena River section).

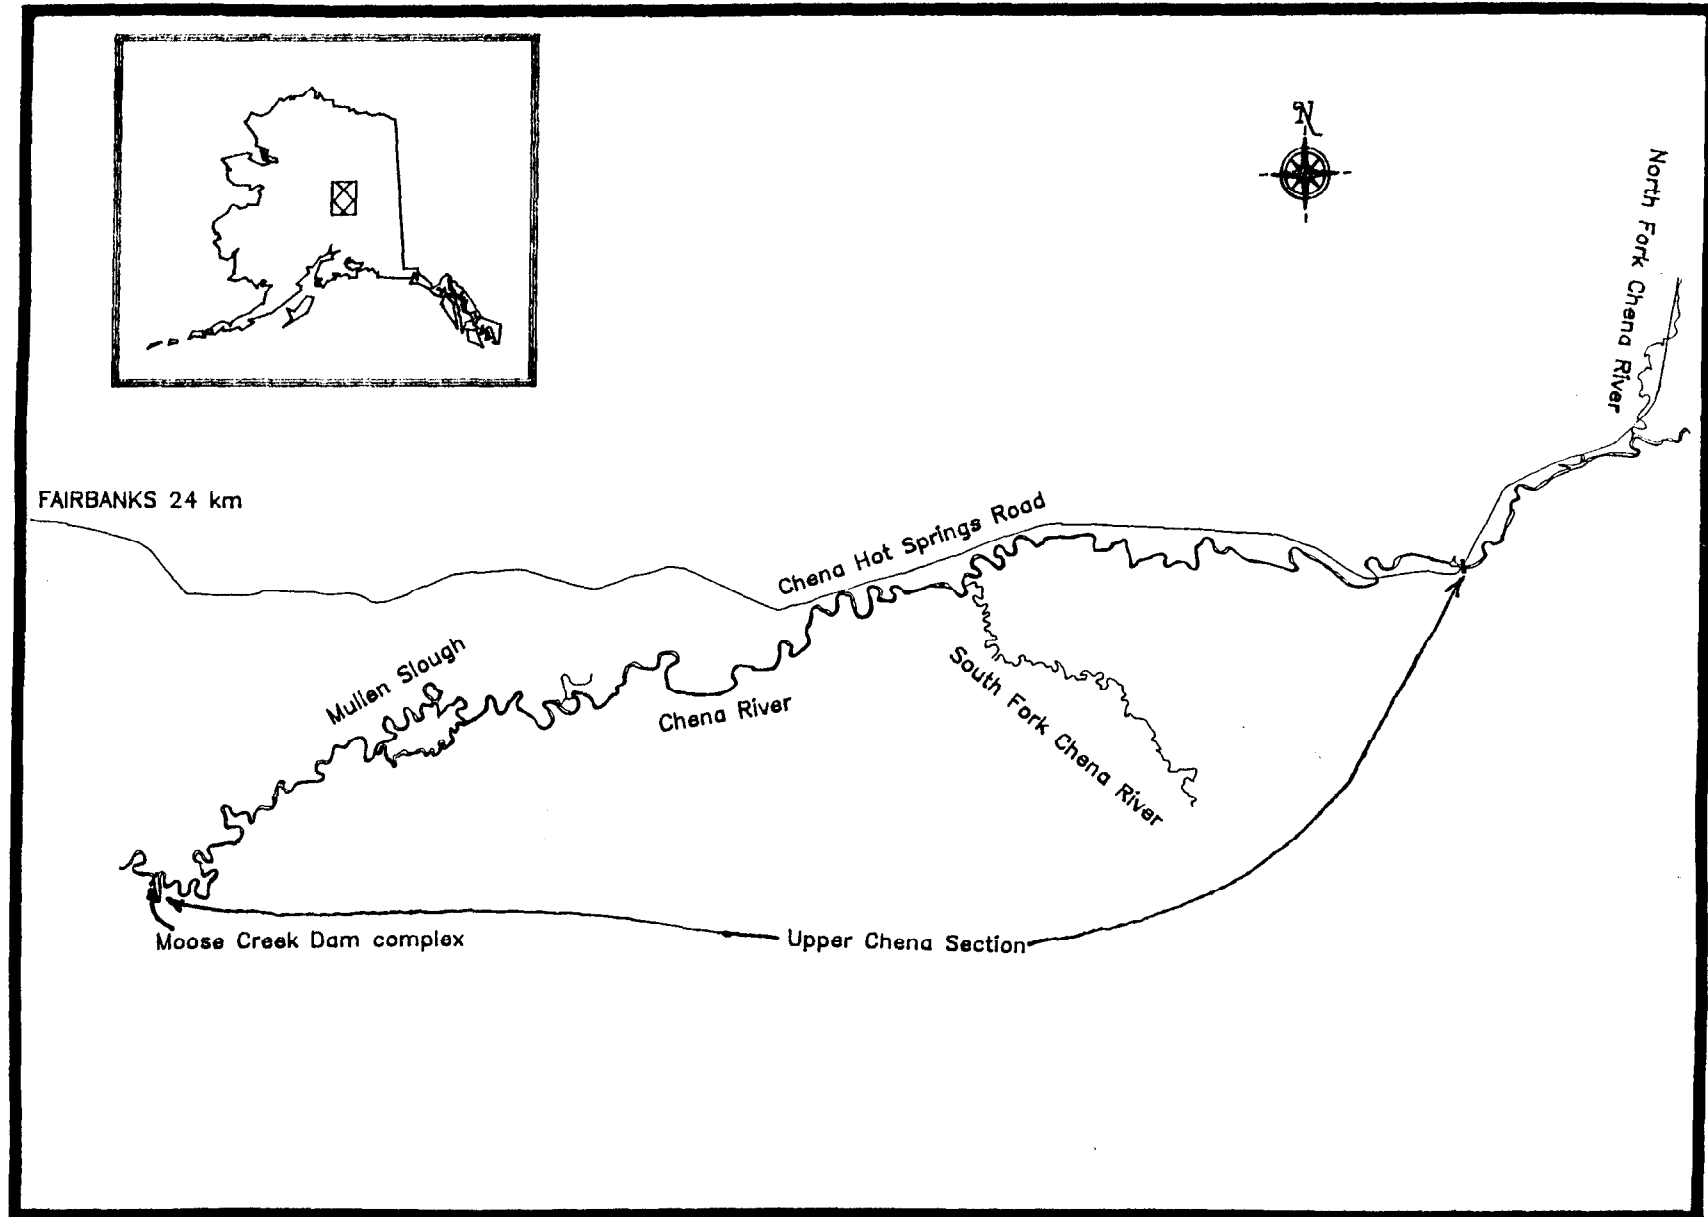

Figure 3. The Chena River above the Moose Creek Dam complex (Upper Chena River section).

Population abundance in the Lower Chena River was estimated by expanding the sample area estimates in each of the two subsections:

$$(1) \quad \hat{N}_i = R_i \hat{\bar{N}}_i$$

where:  $\hat{N}_i$  = the estimated abundance in stratum (subsection)  $i$ ;

$R_i$  = the possible number of sample areas in stratum  $i$ ;

$$\hat{\bar{N}}_i = \frac{\sum_{j=1}^r \hat{N}_{ij}}{r_i} = \text{average abundance in } r \text{ 3.2-km sample areas;}$$

$r_i$  = 2 3.2-km sample areas in stratum  $i$ ;

$\hat{N}_{ij}$  = the abundance of Arctic grayling in sample area  $j$  of stratum  $i$ ;

$i$  = 1, 2 strata (Lower Chena A and Lower Chena B); and,

$j$  = 1, 2 sample areas (A1 and A2, B1 and B2).

Lower Chena A had 12.5 possible 3.2-km sample areas ( $R_1 = 12.5$ ) and Lower Chena B had 10 possible 3.2-km sample areas ( $R_2 = 10$ ). The variance of each subsection abundance estimate was (Cochran 1977):

$$(2) \quad V[\hat{N}_i] = R_i[R_i - r_i] \hat{S}_i^2 + \frac{R_i^2}{r_i^2} \sum_{j=1}^{r_i} V[\hat{N}_{ij}]$$

where:  $V[\hat{N}_i]$  = variance of estimated abundance in stratum  $i$ ;

$$\hat{S}_i^2 = \frac{\sum_{j=1}^{r_i} (\hat{N}_{ij} - \hat{\bar{N}}_i)^2}{r_i(r_i - 1)};$$

$V[\hat{N}_{ij}]$  = variance of estimated abundance in sample area  $j$  of stratum  $i$  (from program CAPTURE); and,

$r_i$  = the number of 3.2-km sample areas sampled in stratum  $i$ .

Equations 1 and 2 were used to estimate abundance and variance in subsections Lower Chena A and Lower Chena B. Equation 2 is probably a conservative estimate of variance for the Lower Chena. Estimated abundance and variance of the Lower Chena section was calculated by summing the subsection (stratum) abundance estimates and summing the variances:

$$(3) \quad \hat{N}_L = \sum_{i=1}^2 \hat{N}_i$$

$$(4) \quad \hat{V}[\hat{N}_L] = \sum_{i=1}^2 \hat{V}[\hat{N}_i]$$

where:  $\hat{N}_L$  = estimate of Arctic grayling abundance in the Lower Chena River; and,  
 $\hat{V}[\hat{N}_L]$  = estimated variance of abundance of Arctic grayling in the Lower Chena River.

#### Upper Chena River:

Abundance of Arctic grayling greater than 149 mm FL was estimated with the modified Petersen estimator of Bailey (1951, 1952). Two electrofishing boats were used to mark Arctic grayling along both banks of the entire 80 km of the Upper Chena River. Marking of fish required four days. After a hiatus of seven days the two electrofishing boats were used in the same way to examine Arctic grayling for marks. The entire experiment was conducted between 25 and 28 July for the first sample and 1 and 4 August for the second (recapture) sample.

Assumptions necessary for accurate estimation of abundance were identical to those listed in the Lower Chena River experiments. Assumption 1 was implicitly assumed because of the large size of the sample area (80 km) and short duration of the experiment (two weeks). Assumptions 2 and 3 were tested with two Kolmogorov-Smirnov statistical tests. The first test compared the length frequency distributions of recaptured Arctic grayling with those captured during the marking run. The second test compared the length frequency distributions of Arctic grayling captured during the marking run with those captured in the recapture run. In addition, sampling was conducted with equal effort along the entire 80 km of river, so it was assumed that all Arctic grayling had equal probability of capture throughout the Upper Chena River section. Assumptions 4 and 5 were assumed to be valid because of double marking of tagged Arctic grayling and rigorous examination of all captured Arctic grayling.

Estimated abundance was calculated from numbers of marked, examined for marks, and recaptured (Bailey 1951; Seber 1982):

$$(5) \quad \hat{N}_U = \frac{M(C+1)}{(R+1)} - 1$$

where: M = the number of Arctic grayling marked and released alive during the first sample;  
C = the number of Arctic grayling examined for marks during the second sample;  
R = the number of Arctic grayling recaptured during the second sample; and,  
 $\hat{N}_U$  = estimated abundance of Arctic grayling during the first sample.

Bailey's (1951, 1952) modification was used instead of the more familiar modification by Chapman (1951) because of the sampling design used on the Upper Chena River section. Seber (1981) found that if the assumption of a random sample for the second sample was false and a systematic sample was taken (for example, a systematic sample of both banks of the Chena River), then the binomial model of Bailey (1951, 1952) is most appropriate. The binomial model will hold in this situation when:

- 1) there is uniform mixing of marked and unmarked fish; and,
- 2) all fish, whether marked or unmarked, have the same probability of capture.

The Upper Chena River section sample design does not allow for thorough mixing of fish marked at the uppermost reaches with those marked in the downstream reaches, although local mixing of marked and unmarked fish probably occurs.

Variance of the abundance estimate was estimated by (Bailey 1951, 1952):

$$(6) \quad V[N_u] = \frac{\hat{N}_u M (C - R)}{[(R + 1)(R + 2)]}.$$

Estimated abundance and variance in the entire Chena River was calculated as the sum of Lower Chena and Upper Chena River estimates:

$$(7) \quad \hat{N} = \hat{N}_L + \hat{N}_u \quad \text{and}$$

$$(8) \quad V[\hat{N}] = V[\hat{N}_L] + V[\hat{N}_u].$$

#### Age and Size Composition

Collections of Arctic grayling for age-length samples were conducted in conjunction with abundance estimation experiments. The Lower Chena River age-length samples were analyzed independently of the Upper Chena River age-length samples. A stratified design was used to derive age composition estimates for the Lower Chena River. This design was identical to the estimator for population abundance except that equations 1 through 5 were further partitioned into age classes. Therefore, abundance of age  $k$  Arctic grayling in the Lower Chena was estimated by equations 1 through 5. Using the estimates of abundance for age  $k$  ( $k = 1, 2, 3, \dots, n$  age classes) and the abundance estimates ( $N_i$ 's), age composition of the Lower Chena River was estimated. First the proportions for each age class were estimated in each of the two sample areas for each of the two subsections of the Lower Chena:

$$(9) \quad p_{ijk} = \frac{y_{ijk}}{n_{ij}}$$

where:  $y_{ijk}$  = the number of age  $k$  Arctic grayling sampled in sample area  $j$  of subsection (stratum)  $i$ ; and,  
 $n_{ij}$  = the number of Arctic grayling sampled in sample area  $j$  of subsection  $i$ .

The variances of the proportions were estimated by:

$$(10) \quad V[\hat{p}_{ijk}] = \frac{\hat{p}_{ijk} (1 - \hat{p}_{ijk})}{n_{ij} - 1}$$

The sample area abundance estimates were used to weight each of the marginal proportions from the respective sample area:

$$(11) \quad \hat{N}_{ijk} = \hat{N}_{ij} \hat{p}_{ijk}$$

where:  $\hat{N}_{ijk}$  = the estimated abundance of age  $k$  Arctic grayling in sample area  $j$  of stratum  $i$ .

The variance of this product was approximated by Goodman (1960):

$$(12) \quad V[\hat{N}_{ijk}] = \hat{p}_{ijk} V[\hat{N}_{ij}] + \hat{N}_{ij} V[\hat{p}_{ijk}] - V[\hat{p}_{ijk}] V[\hat{N}_{ij}]$$

By substituting  $\hat{N}_{ijk}$  and  $V[\hat{N}_{ijk}]$  for  $N_{ij}$  and  $V[N_{ij}]$  in equations 1 through 5, the resulting abundance estimates by age class ( $N_{Lk}$ 's) were used to estimate age composition for the Lower Chena River.

Proportion of the population by age class was calculated as:

$$(13) \quad \hat{p}_{Lk} = \hat{N}_{Lk} \div \hat{N}_L$$

where:  $\hat{p}_{Lk}$  = the proportion of age  $k$  Arctic grayling in the Lower Chena River;  
 $\hat{N}_{Lk}$  = the abundance of age  $k$  Arctic grayling in the Lower Chena River (from substitution into equations 1 through 4); and,  
 $\hat{N}_L$  = the abundance of Arctic grayling in the Lower Chena River.

Bernard (1983) approximated the variance of the quotient of two dependent variables as (ignoring hat symbols):

$$(14) \quad V[p_{Lk}] = \left[ \frac{N_{Lk}}{N_L} \right]^2 \left[ \frac{V[N_{Lk}]}{N_{Lk}^2} + \frac{V[N_L]}{N_L^2} - \frac{2V[N_{Lk}]}{N_L N_{Lk}} \right]$$

Age composition of Upper Chena River Arctic grayling was calculated directly from age-length samples taken during the first sample of the mark-recapture estimate. The proportions and variances at age were calculated using equations 9 and 10 (disregarding subscripts for sample areas and strata).

Estimates of age composition were then used to apportion the Upper Chena River population abundance estimate and its variance using equations 11 and 12. The resulting abundance estimates at age  $k$  ( $N_{uk}$ 's) and variances ( $V[N_{uk}]$ 's) were then added to the corresponding  $N_{lk}$  and  $V[N_{lk}]$  to estimate abundance at age in the entire Chena River. Age composition and variance in the entire Chena River was then estimated by equations 13 and 14.

Size composition of Arctic grayling in the Chena River was characterized by the Relative Stock Density (RSD) indices of Gabelhouse (1984). The RSD categories for Arctic grayling are: "stock" (150 to 269 mm FL); "quality" (270 to 339 mm FL); "preferred" (340 to 449 mm FL); "memorable" (450 to 559 mm FL); and "trophy" (greater than 559 mm FL). Estimation of RSD for the Chena River follows that of age composition estimates (equations 1 through 14). RSD estimates and variances were calculated by substituting "age class  $k$ " with "RSD category  $k$ ". Similarly, the Upper Chena River and entire Chena River estimates and variances were calculated with equations 9 through 14.

### Growth

Growth of Chena River Arctic grayling was modelled with the von Bertalanffy growth equation (Ricker 1975), a nonlinear least-squares method. Age-length data collected between 1986 and 1988 were used to model growth. All samples were taken with the electrofishing boat during mark-recapture experiments in the months of June and July.

Mean length at age was calculated as the arithmetic mean fork length at each age for samples taken from 1986 to 1988. Variances were calculated using the normal distribution theory. The Marquardt (1963) compromise was used to fit the three parameters of the von Bertalanffy growth equation. These parameters are:

- 1)  $L_{\infty}$  is the length an average fish would achieve if it continued to live and grow indefinitely (Ricker 1975);
- 2)  $K$  is a constant that determines the rate of increase of growth increments (Ricker 1975); and,
- 3)  $t_0$  represents the hypothetical age at which a fish would have zero length (Ricker 1975).

By allowing the parameters to range from 350 to 600 mm FL by 50 mm increments for  $L_{\infty}$ ; from 0.0 to 0.4 by 0.1 for  $K$ ; and from -2.0 to 2.0 by 0.5 for  $t_0$ , the model was fitted a total of 270 times. The model with the smallest squared deviations provided the starting parameters for iterative solution of the equation. The resulting growth equation was compared to growth equations derived from data collected on Arctic grayling in the Salcha and Chatanika Rivers (Clark 1989). Comparisons of growth equations were made with Hotteling's  $T^2$  as described by Bernard (1981).

### Survival and Recruitment

As of 1988, three years of population abundance and age composition estimates had been completed for the lower 152 km of the Chena River. These estimates were used to estimate survival and recruitment for two time periods; between 1986 and 1987, and between 1987 and 1988. Survival rate and recruitment were calculated for the Arctic grayling population defined as: "those Arctic grayling in the lower 152 km of the Chena River that are age 3 and older".

Annual recruitment was defined as the number of age 3 Arctic grayling added to the population between year  $i$  and year  $i+1$  and alive in year  $i+1$ . Estimates of recruitment were calculated with population abundance estimates and estimates of the proportion of age 3 Arctic grayling in 1987 and 1988:

$$(15) \quad \hat{A}_{i,i+1} = \hat{N}_{i+1} \hat{p}_{3,i+1}$$

where:  $\hat{A}_{i,i+1}$  = recruits entering the population between year  $i$  and year  $i+1$  and alive in year  $i+1$ ;  
 $\hat{N}_{i+1}$  = number of fish age 3 and older in the population in year  $i+1$ ; and,  
 $\hat{p}_{3,i+1}$  = the proportion of age 3 Arctic grayling in the population in year  $i+1$ .

Variance of annual recruitment was estimated with equation 12, the variance of a product. With recruitment and population abundance estimates in years  $i$  and  $i+1$ , one can estimate survival rate between year  $i$  and year  $i+1$ :

$$(16) \quad \hat{S}_{i,i+1} = \frac{\hat{N}_{i+1} - \hat{A}_{i,i+1}}{\hat{N}_i}$$

The variance of annual survival was approximated as the variance of a quotient of two independent variables with the delta method (Seber 1982; ignoring hat symbols):

$$(17) \quad V[S] = \left[ \frac{N'_{i+1}}{N_i} \right]^2 \left[ \frac{V[N'_{i+1}]}{N'^2_{i+1}} + \frac{V[N_i]}{N_i^2} \right]$$

where:  $N'_{i+1} = N_{i+1} - A_{i,i+1}$ ; and,

$$V[N'_{i+1}] = V[N_{i+1}] + V[A_{i,i+1}].$$

### Historic Data Summaries

Data collected from the Chena River (1955 to 1988) were summarized in Appendix A. Creel census estimates, population abundance estimates, length at age estimates, age composition estimates, and size composition estimates were summarized from Federal Aid in Sport Fish Restoration reports and State of Alaska Fishery Data Series reports written from 1959 to the present

(Appendix A). When possible, estimates of precision were reported with point estimates. Precision was reported as either standard error or 95% confidence interval. Sample sizes were reported if neither of these estimates of precision were available. Length frequency was generally reported in the literature as numbers sampled per 10 mm length increment. The length frequency distributions were converted into the RSD categories of Gabelhouse (1984) for comparison with data collected from 1986 to 1988. In addition to the aforementioned reports in Appendix A, Arctic grayling migration studies were summarized in a report by Tack (1980). Reports concerning Arctic grayling research from 1952-1980 were compiled by Armstrong (1982). In addition, Armstrong et al. (1986) have compiled a bibliography for the genus *Thymallus* to 1985.

## RESULTS

### Lower Chena River

A total of 627 Arctic grayling ( $\geq 150$  mm FL) was captured during mark-recapture experiments in the Lower Chena River. Twelve mortalities or serious injuries were recorded for an overall injury rate of 1.9% (SE = 0.5%).

Although no significant changes in capture probabilities by length of fish occurred during population estimation (Figure 4), program CAPTURE detected significant changes in behavior of marked Arctic grayling as the experiments progressed (Table 2). In two sample areas, variability in capture probability was attributed to two causes (see White et al. 1982). In sample area A1, CAPTURE found both temporal and behavioral components to change in capture probability during the experiment. Looking at the Kolmogorov-Smirnov plots of cumulative distributions (CDF; Figure 4), a change in capture probability was evident at approximately 219 mm FL. Although the two distributions were not significantly different, complete stratification of the experiment at 219 mm FL resulted in two separate populations for which CAPTURE could provide valid estimators. The estimate for small Arctic grayling contained a significant temporal component to changing capture probabilities (estimated abundance = 430). The estimate for large Arctic grayling contained primarily a behavioral component to changing capture probabilities (estimated abundance = 107). Estimated abundance in sample area A1 was 537 Arctic grayling (SE = 129 Arctic grayling,  $CV^2 = 24.0\%$ ; Table 2)

The same pattern of change in capture probabilities was evident in sample area B1. In this case the mark-recapture data were stratified at 234 mm FL as indicated by the CDF plot (Figure 4). No significant changes in capture probability were detected for small Arctic grayling (estimated abundance = 241). Large Arctic grayling in sample area B1 exhibited a behavioral change in capture probability (estimated abundance = 82). Estimated abundance in sample area B1 was 323 Arctic grayling (SE = 80 Arctic grayling,  $CV = 24.8\%$ ; Table 2).

---

<sup>2</sup> CV = standard error (SE) divided by the point estimate expressed as a percentage.

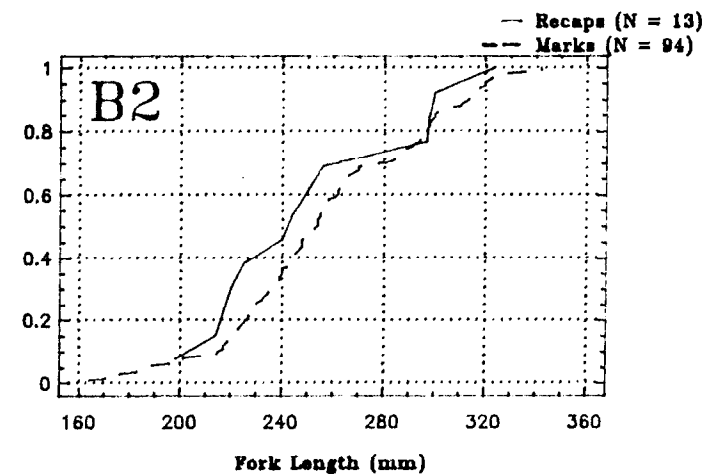

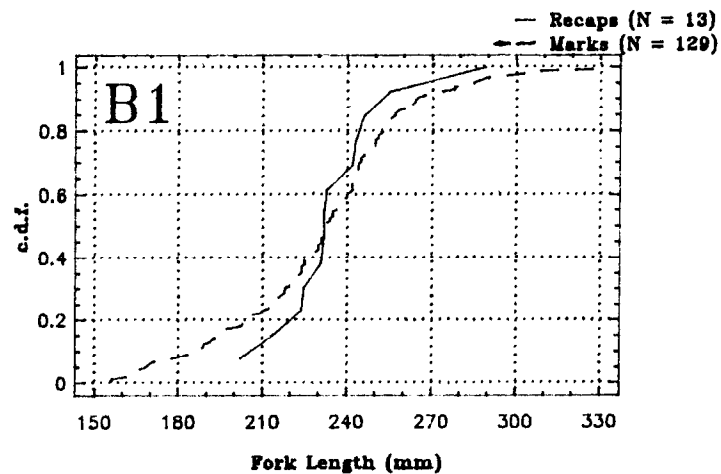

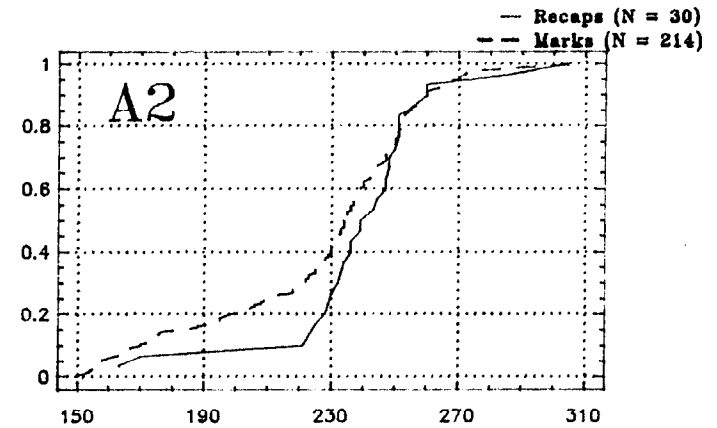

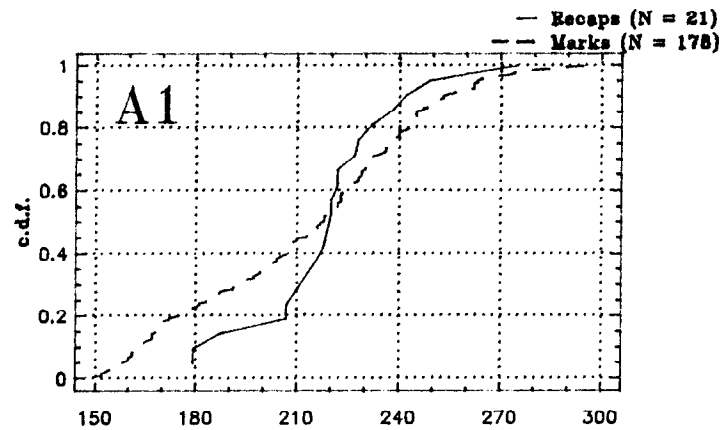

Figure 4. Cumulative distribution functions (c.d.f.) of lengths of Arctic grayling marked versus lengths of Arctic grayling recaptured for four 3.2-km sample areas of the Lower Chena section of the Chena River, 26 June through 8 July 1988. Kolmogorov-Smirnov test statistics and tail probabilities for each sample area are: A1(DN = 0.275; P = 0.11); A2(DN = 0.233, P = 0.11); B1(DN = 0.219, P = 0.99); and, B2(DN = 0.192, P = 0.99). N = sample size.

Table 2. Summary of sample area abundance estimates of Arctic grayling ( $\geq 150$  mm FL) in the Lower Chena section of the Chena River, 26 June through 8 July, 1988.

Subsection	River KM	CAPTURE Model <sup>1</sup>	Abundance Estimate	Standard Error	Fish/km
A1	14.4 to 17.6	$M_t, M_{bh}$ <sup>2</sup>	537	129	168
A2	22.4 to 25.6	$M_b$	347	56	108
B1	48.0 to 51.2	$M_o, M_b$ <sup>3</sup>	323	80	101
B2	57.6 to 60.8	$M_b$	124	17	39

<sup>1</sup> Models selected by program CAPTURE as most appropriate:

$M_t$  : time varying probability of capture;

$M_{bh}$  : behavioral and heterogeneous changes in probability of capture;

$M_b$  : behavioral changes in probability of capture; and,

$M_o$  : constant probability of capture.

These models and their estimators are described in White et al. (1982) and Otis et al. (1978).

<sup>2</sup> Model  $M_t$  was chosen for fish greater than 149 mm FL and less than 220 mm FL. Model  $M_{bh}$  was chosen for fish greater than 219 mm FL.

<sup>3</sup> Model  $M_o$  was chosen for fish greater than 149 mm FL and less than 235 mm FL. Model  $M_b$  was chosen for fish greater than 234 mm FL.

In sample areas A2 and B2, program CAPTURE estimated population abundance without stratification by length. In sample areas A2 and B2 a significant behavioral component caused a change in capture probability. Model  $M_b$  (Otis et al. 1978) was chosen as most appropriate for both sample area abundance estimates. Estimated abundance in sample area A2 was 347 Arctic grayling (SE = 56 Arctic grayling, CV = 16.1%; Table 2). Estimated abundance in sample area B2 was 124 Arctic grayling (SE = 17 Arctic grayling, CV = 13.7%; Table 2).

Expansion of estimated abundance in sample areas A1 and A2 resulted in an estimated population size of 5,525 Arctic grayling in subsection A of the Lower Chena River (Table 3). Expansion of estimates in sample areas B1 and B2 to all of subsection B resulted in an estimate of 2,235 Arctic grayling (Table 3). Estimated abundance of Arctic grayling in the Lower Chena River was 7,760 fish (SE = 1,707 fish, CV = 22.0%).

Age composition of samples taken from sample areas A1 and A2 of subsection A of the Lower Chena River were significantly different ( $\chi^2 = 35.45$ ,  $df = 4$ ,  $P < 0.005$ ; Figure 5, Table 4). A significant difference was also found in samples taken from sample areas B1 and B2 of subsection B ( $\chi^2 = 20.85$ ,  $df = 6$ ,  $P < 0.005$ ; Figure 5, Table 4). Therefore, age composition data were expanded by sample area to adjust for differences in age composition within subsections. Age 5 Arctic grayling dominated the estimated age composition of the Lower Chena River in 1988. Of the estimated 7,760 Arctic grayling in the Lower Chena River, 3,126 fish (SE = 653 fish, CV = 20.9%), or 40.3% were age 5 (Table 4). Abundances of age 2 through age 4 Arctic grayling were similar. The abundance estimate for age 2 fish was most likely biased because of the imposed lower length limit for mark-recapture experiments (150 mm FL). The estimate of age 3 abundance probably reflected the true abundance of this age class. Very few Arctic grayling older than age 5 were found in the Lower Chena River (Table 4).

Size composition samples taken from subsection A were not significantly different ( $\chi^2 = 0.44$ ,  $df = 1$ ,  $P > 0.50$ ; Figure 6, Table 5). However, size composition estimates in the two sample areas in subsection B were significantly different ( $\chi^2 = 23.14$ ,  $df = 1$ ,  $P < 0.005$ ; Figure 6, Table 5). Therefore, size composition data were expanded by sample area to adjust for differences in size composition within subsection B. Ninety-two percent of Arctic grayling greater than 149 mm FL were also less than 270 mm FL (Table 5). Of the 594 Arctic grayling (SE = 104 fish, CV = 17.5%) greater than 270 mm FL, only 10 fish (SE = 12 fish, CV = 120.0%) were of preferred size ( $\geq 340$  mm FL). No memorable or trophy size Arctic grayling were sampled from the Lower Chena River.

#### Upper Chena River

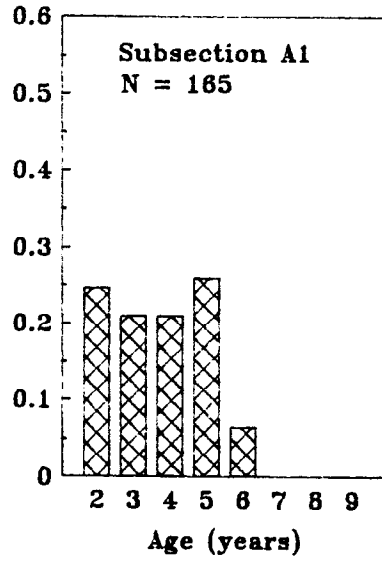

A total of 2,495 Arctic grayling ( $\geq 150$  mm FL) was captured during the mark-recapture experiment on the Upper Chena River. Twenty-eight mortalities or serious injuries were recorded for an overall injury rate of 1.1% (SE = 0.2%).

During 25 through 28 July, 1,291 Arctic grayling ( $\geq 150$  mm FL) were marked along 80 km of the Upper Chena River. During 1 through 4 August, 1,307 Arctic

<sup>1</sup> Minimum lengths for RSD categories are (Gabelhouse 1984):

Stock - 150 mm FL; Quality - 270 mm FL; Preferred - 340 mm FL;

Memorable - 450 mm FL; and, Trophy - 560 mm FL.

<sup>2</sup> Subsections are: A1 - River kilometer 14.4 to 17.6; A2 - River kilometer 22.4 to 25.6; B1 - River kilometer 48.0 to 51.2; and, B2 - River kilometer 57.6 to 60.8.

<sup>3</sup> Abundance is the estimated abundance in a 3.2 km subsection.

<sup>4</sup> Abundance is the expanded abundance estimate in the lower 72.0 km of the Chena River by RSD category.

grayling were examined for marks along the same 80 km section of river. A total of 116 Arctic grayling was recaptured during the second sample. No significant difference was found between the CDF of lengths of marked Arctic grayling and the CDF of lengths of recaptured Arctic grayling ( $DN^3 = 0.11$ ,  $P = 0.13$ ). Therefore, the second sample was unbiased with respect to equal probability of capture of marked Arctic grayling by size (Figure 7B) and a single population estimate would suffice. The modified Petersen estimate of Bailey (1951, 1952) was 14,444 fish ( $SE = 1,210$  fish,  $CV = 8.4\%$ ).

The CDF of lengths of marked Arctic grayling was significantly different than the CDF of lengths of Arctic grayling examined for marks ( $DN = 0.065$ ,  $P = 0.007$ ), although no functional difference was evident (Figure 7A). It was therefore judged that age-length samples taken during the marking event could be used to directly estimate age and size compositions of Arctic grayling in the Upper Chena River. Age 5 Arctic grayling dominated the sample from the Upper Chena River, representing 43.6% of all fish sampled (Table 6). Age 3 and age 8 fish were next most abundant, accounting for 14.2% and 9.6% of the population, respectively.

Size composition of Arctic grayling in the Upper Chena River was split equally among stock size and quality size fish (Table 7). Over 50% of Arctic grayling greater than 149 mm FL were also greater than 269 mm FL. No memorable or trophy size Arctic grayling were sampled on the Upper Chena River.

#### Chena River

The summed estimate of Arctic grayling abundance in the lower 152 km of the Chena River was 22,204 fish ( $SE = 2,092$  fish,  $CV = 9.4\%$ ). Of these fish, 42.4% were age 5, representing an abundance of 9,423 fish (Table 8). The next most abundant age class was age 3, totalling 3,373 fish or 15.2%. Although not fully recruited to the mark-recapture estimates, age 2 Arctic grayling represented 8.7% of the estimated abundance or 1,936 fish ( $SE = 533$  fish,  $CV = 27.5\%$ ). Of the 22,204 Arctic grayling greater than 149 mm FL, 62.7% or 13,923 fish were less than 270 mm FL (Table 7). Of the remaining 8,281 fish that were greater than 269 mm FL, 1,200 fish ( $SE = 127$  fish,  $CV = 10.6\%$ ) were also greater than 339 mm FL.

The von Bertalanffy growth model was successfully adapted to Chena River Arctic grayling collected from 1986 through 1988 (Table 9). Standard deviation of mean fork length was stable among all ages of fish sampled, although more samples were needed from age 10 and age 11 fish (Table 10). Growth of Chena River Arctic grayling was significantly different than Arctic grayling collected from either the Salcha River (Clark, in prep.;  $T^2 = 121.53$ ;  $df = 3$  and 5,495;  $P < 0.01$ ) or the Chatanika River (Clark, in prep.;  $T^2 = 90.93$ ;  $df = 3$  and 5,766;  $P < 0.01$ ) during the same three year time span.

Population size (age 3 and older) in summer of 1986 was 61,581 fish ( $SE = 26,987$  fish,  $CV = 43.8\%$ ). Annual recruitment from summer 1986 to summer 1987 was 2,526 fish ( $SE = 358$  fish,  $CV = 14.2\%$ ). Population size in summer of 1987 was 29,580 fish ( $SE = 3,525$  fish,  $CV = 11.9\%$ ). Annual survival was

<sup>3</sup> DN = test statistic for the Kolmogorov-Smirnov test.

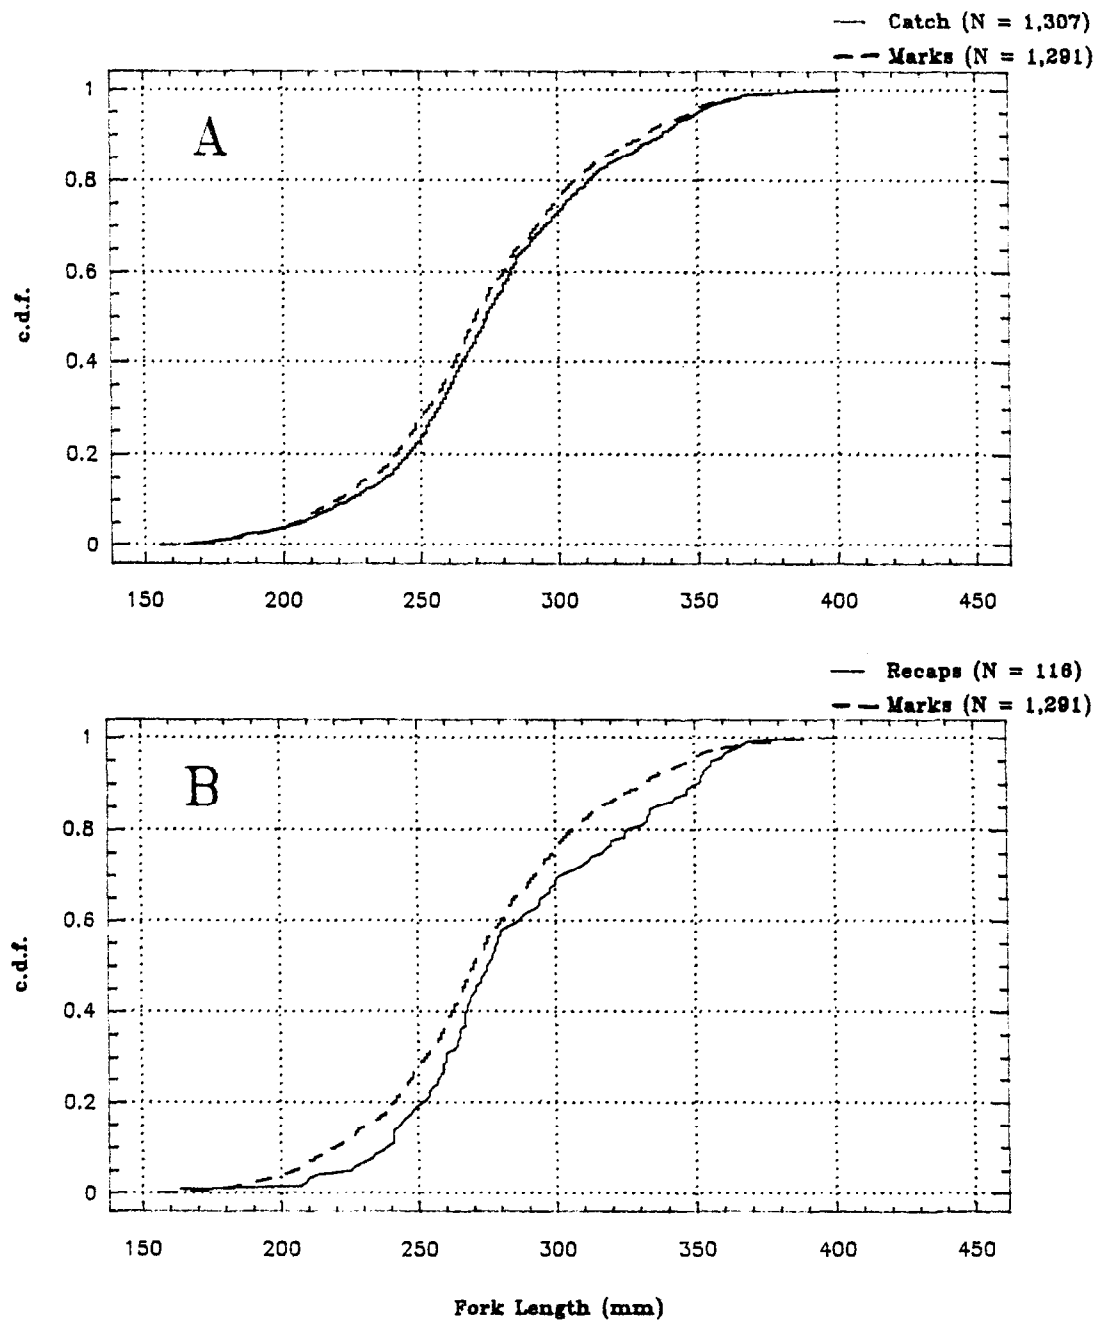

Figure 7. Cumulative distribution functions of lengths of Arctic grayling marked versus lengths of Arctic grayling examined for marks (A) and versus lengths of Arctic grayling recaptured (B) for the Upper Chena section of the Chena River, 28 July through 4 August 1988. Kolmogorov-Smirnov test statistics and tail probabilities are: A(DN = 0.065, P = 0.007); and, B(DN = 0.114, P = 0.126).

Table 6. Estimates of age composition and abundance by age class with standard errors for Arctic grayling ( $\geq 150$  mm FL) captured by pulsed-DC electrofishing from the Upper Chena section of the Chena River, 25 to 28 July, 1988.

<sup>1</sup> Lower Chena section - River kilometer 0 to 72.0.

<sup>2</sup> Upper Chena section - River kilometer 72.0 to 152.0.

<sup>3</sup> Chena River - River kilometer 0 to 152.0.

<sup>4</sup> p = estimated proportion of Arctic grayling at age in the section.

<sup>5</sup> SE = estimated standard error of p.

<sup>6</sup> N = estimated population abundance of Arctic grayling at age in the section.

<sup>7</sup> SE = estimated standard error of N.

Table 9. Parameter estimates and standard errors of the von Bertalanffy growth model<sup>1</sup> for Arctic grayling from the Chena River, 1986-1988.

Parameter	Estimate	Standard Error
$L_{\infty}$	538	21
$K$	0.096	0.007
$t_0$	-1.716	0.111
$Corr(L_{\infty}, K)$	-0.993	---
$Corr(L_{\infty}, t_0)$	-0.906	---
$Corr(K, t_0)$	0.947	---
Sample size	4,301	

<sup>1</sup> The form of the von Bertalanffy growth model (Ricker 1975) is as follows:  $l_t = L_{\infty} (1 - \exp(-K (t - t_0)))$ . The parameters of this model were estimated with data collected during 1986 through 1988. Estimation was accomplished through nonlinear regression using the Marquardt compromise (Marquardt 1963).

Table 10. Mean fork length at age of Arctic grayling from the Chena River, 1986-1988.

Age	n <sup>1</sup>	FL <sup>2</sup>	SD <sup>3</sup>	SE <sup>4</sup>
1	99	130	27	3
2	311	168	22	1
3	1,092	192	23	1
4	951	227	23	1
5	932	260	23	1

8	162	324	26	2
9	71	342	28	3
10	10	341	22	7
11	5	368	27	12
Totals	4,301	235	54	1

<sup>1</sup> n is the total number of fish aged from samples taken in 1986, 1987, and 1988.

<sup>2</sup> FL is the arithmetic mean fork length in millimeters.

<sup>3</sup> SD is the sample standard deviation of FL.

<sup>4</sup> SE is the standard error of FL.

estimated as 43.9% (SE = 20.1%, CV = 45.8%) between 1986 and 1987. Annual recruitment from summer 1987 to summer 1988 was 3,373 fish (SE = 529 fish, CV = 15.7%). Population size in summer of 1988 was 20,268 fish (SE = 1,214 fish, CV = 6.0%). Annual survival was estimated as 57.1% (SE = 8.1%, CV = 14.2%) between 1987 and 1988.

## DISCUSSION

The sampling designs presented in this report were adequate for the precise estimation of population abundance, and age and size compositions. The objective criterion for population estimation was for the estimate to be within  $\pm 25\%$  of the true abundance 95% of the time. Although a 95% confidence interval was not calculated for this estimate, a coefficient of variation of 12% or less would meet or exceed the objective criterion. The coefficient of variation of estimated population abundance was 9.4%, although the imprecision of the Lower Chena River abundance estimate reduced overall precision. Imprecision of sample area abundance estimates was the cause of imprecision in the Lower Chena population estimate, although differences in population size within subsections accounted for a large portion of the variation in estimation (see Tables 2 and 3). Precision of the Chena River abundance estimate was primarily dependent on precision of the Upper Chena section estimate. High numbers of recaptures in the Upper Chena section relative to the Lower Chena section resulted in greater precision of the abundance estimate in the Upper Chena section.

If population size in the Lower Chena is truly unrelated to sample areas chosen, then a stratified design would not be as efficient in estimating population size for the entire Lower Chena section. If the four sample areas discussed in this report were truly randomly chosen, without regard for river subsection, then the estimated abundance would have been 7,487 fish with a standard error of 1,950 fish. From Table 2, one can see that population estimates in sample areas A2 and B1 were more similar than either A1 or B2, respectively. Improper construction of strata could reduce precision, (and possible accuracy) especially when the true distribution of population sizes by river section is entirely random.

Age and size compositions were estimated with high precision, primarily because of the high numbers of Arctic grayling sampled during mark-recapture experiments. Thompson (1987) recommended that a sample of at least 400 be taken to estimate multinomial proportions with sufficient precision (all proportions are within 10% of the true proportions 95% of the time, corresponding to a coefficient of variation of 5% or less). Over 1,000 samples were used for age composition in the Upper Chena River, so that standard errors are small for each proportion (Tables 6 and 8). However, because of the stratified design in the Lower Chena River and significant differences in age composition by sample area, standard errors were large for each proportion (Tables 4 and 8; Figure 5). Additional variation in age composition was introduced by variation due to the mark-recapture estimate and stratified design. Sample size by sample area ranged from 81 to 192 ages, hardly enough to satisfy Thompson's (1987) statistical criterion for each sample area. If age compositions were similar among sample areas, the data

could have been pooled and weighted by abundance alone (ignoring between strata variance) as was reported by Clark and Ridder (1988) in 1987.

Estimates of size composition in the Upper Chena River were relatively precise (Table 7). Sample size for the length frequency was over 2,000 in the Upper Chena River. However, RSD estimates in the Lower Chena suffered from small sample size by sample area (Table 5). Length data could have been pooled among sample areas, but one area (area B2) had a significantly different length frequency from all other sample areas (Table 5; Figure 6).

The ultimate goal of stock assessment research on the Chena River is to predict the effect of the recreational fishery on the Arctic grayling stock. Predictions can be made by analytically modelling stock dynamics and the fishery. By artificially manipulating the fishery, the consequences of management can be inferred from changes in the status of the stock. If the analytical model suffers from inadequate data input, predicted stock status output will also be inadequate. Inadequate data input is the result of a poor sampling design or the vagaries of sampling biological populations. As estimates of population abundance and age composition become more reliable, estimates of survival, fishing mortality, natural mortality, and annual recruitment will become more reliable. For example, estimated survival rate between 1986 and 1987 was imprecise (CV = 45.8%), although estimated survival between 1987 and 1988 was relatively precise (CV = 14.2%). Imprecision in the first estimate is due to imprecision in the 1986 estimate of abundance alone, since the 1987 abundance estimate was also used in the second estimate of survival. The 1986 abundance estimate was imprecise because of a poor sampling design (Clark and Ridder 1987b, 1988).

#### ACKNOWLEDGEMENTS

The author wishes to thank William Ridder, Mark Ross, James Harrild, Timothy Viavant, and James Chumbley for their expertise in the field. Thanks also go to David Bernard for aid in the development of statistical procedures that are exposed in this report. John H. Clark and Rolland Holmes are to be commended for their supervisory and coordination roles that provided the structure necessary for a successful field season and reporting process. This project and report were made possible by partial funding provided by the U.S. Fish and Wildlife Service through the Federal Aid in Sport Fish Restoration Act (16 U.S.C. 777-777K) under project F-10-4, Job Number G-8-1.

## APPENDIX A

Appendix Table A1. Source citations for Federal Aid and Fishery Data Reports used for data summaries, 1955-1988.

Year	Type of Data <sup>1</sup>	Source Document
1955	CC	Warner (1959)
1956	CC	Warner (1959)
1957	CC	Warner (1959)
1958	CC	Warner (1959)
1967	AL, CC, POP	Van Hulle (1968)
1968	AL, CC, POP	Roguski and Winslow (1969)
1969	AL, CC, POP	Roguski and Tack (1970)
1970	CC, POP	Tack (1971)
1971	POP	Tack (1972)
1972	CC, POP	Tack (1973)
1973	AL, POP	Tack (1974)
1974	AL, CC, POP	Tack (1975)
1975	AL, CC, POP	Tack (1976)
1976	AL, CC, POP	Hallberg (1977)
1977	AL, CC, POP	Hallberg (1978)
1978	AL, CC, POP	Hallberg (1979)
1979	AL, CC, POP	Hallberg (1980)
1980	AL, CC, POP	Hallberg (1981)
1981	AL, CC, POP	Hallberg (1982)
1982	AL, CC, POP	Holmes (1983)
1983	AL, CC, POP	Holmes (1984)
1984	AL, CC, POP	Holmes (1985)
1985	AL, CC, POP	Holmes et al. (1986)
1986	CC	Clark and Ridder (1987a)
	AL, POP	Clark and Ridder (1987b)
1987	CC	Baker (1988)
1987	AL, POP	Clark and Ridder (1988)
1988	CC	Baker (in prep.)
	AL, POP	Clark (this report)

<sup>1</sup> CC = Creel census estimates;  
AL = age and size composition estimates; and,  
POP = population abundance estimates.

Appendix Table A2. Chena River study sections used from 1968 to 1985<sup>1</sup>.

Section Number	Section Name	River Kilometers	Length in Kilometers
1	River mouth to University Ave.	0-9.6	9.6
2A	University Ave. to Peger Road	9.6-12.8	3.2
2B	Peger Road to Wendell Street	12.8-17.6	4.8
3	Wendell St. to Wainwright Bridge	17.6-23.2	5.6
4	Wainwright Bridge to Badger Slough	23.2-34.4	11.2
5	Badger Slough		26.4
6	Badger Slough to Little Chena R.	34.4-39.2	4.8
7	Little Chena River		98.4
8	Little Chena to Nordale Slough	39.2-49.6	10.4
DS	Nordale Slough to Bluffs	49.6-88.8	39.2
9B	Bluffs to Bailey Bridge	88.8-100.8	12.0
10	Bailey Bridge to Hodgins Slough	100.8-126.4	25.6
11	Hodgins Slough to 90 Mi. Slough	126.4-144.0	17.6
12	90 Mi. Slough to First Bridge	144.0-147.2	3.2
13	First Bridge to Second Bridge	147.2-151.2	4.0
14	Second Bridge to North Fork	151.2-163.2	12.0
15	North Fork of Chena River		56.0
16	East Fork of Chena River		99.2
17	West Fork of Chena River		56.0

<sup>1</sup> Taken from Hallberg 1980.

	7/22-7/31	10B	SN	1,156/km	304-3,035
	6/12-6/24	12	SN	1,092/km	552-1,643
1986	7/7-8/6	WC	EXP	61,581	SE = 26,987
1987	6/27-7/30	WC	EXP+P	31,502	SE = 3,500
1988	6/26-8/4	WC	EXP+P	22,204	SE = 2,092

<sup>1</sup> Areas are taken from Hallberg (1980); WC = Whole Chena River (lower 152 km).

<sup>2</sup> Estimators are: SN = Schnabel; SE = Schumacher-Eschmeyer; P = Petersen (Ricker 1975); EXP = Expanded estimates (Clark and Ridder 1987a); EXP+P = expanded estimates and a Petersen estimate (Clark and Ridder 1988).

<sup>3</sup> Confidence is either the 95% confidence interval or the Standard Error (SE) of the estimate.

Appendix Table A4. Summary of Arctic grayling creel census on the Chena River, 1955 through 1988.

Year	Dates	Area	Angler hours	Harvest	CPUE	Mean Length
1955	ND	Lower Chena	---	---	0.89	226
1956	ND	Lower Chena	---	---	0.95	251
1957	ND	Lower Chena	---	---	0.62	246
1958	ND	Lower Chena	---	---	0.88	226
1967	4/10 to 8/11	Entire Chena	12,885	---	0.32	245
1968	5/1 to 9/2	Entire Chena	10,269	5,643	0.55	251
1969	7/1 to 9/30	Entire Chena	7,998	7,686	0.96	263
1970	5/1 to 5/30 and 7/1 to 8/31	Entire Chena	12,518	6,770	0.54	---
1972	5/25 to 8/27	Lower Chena	13,116	10,099	0.77	---
1974	7/1 to 8/31	Upper Chena	11,680	18,049	1.72	---
1975	6/1 to 8/31	Upper Chena	22,657	14,067	0.62	252
1976	6/1 to 8/31	Upper Chena	10,762	4,161	0.39	230
1977	6/1 to 8/31	Upper Chena	13,563	9,406	0.71	208
1978	5/29 to 8/31	Upper Chena	10,508	6,898	0.65	222
1979	6/1 to 8/31	Upper Chena	12,564	8,544	0.69	240
1980	5/8 to 9/30	Upper Chena	20,827	16,390	0.78	256

Standard Error	0.043	0.034	0.005	0.000	0.000

<sup>1</sup> Minimum lengths for RSD categories are (Gablehouse 1984):

Stock - 150 mm FL; Quality - 270 mm FL; Preferred - 340 mm FL;

Memorable - 450 mm FL; and, Trophy - 560 mm FL.

<sup>2</sup> Year (sections sampled (taken from Hallberg 1980)) - sampling dates.

<sup>3</sup> Lengths were taken in 1985, but not reported in Holmes et al. (1986).

<sup>4</sup> RSD was adjusted to correct for bias due to the electrofishing boat (Clark and Ridder 1988).

<sup>5</sup> Standard error is for adjusted RSD only.

<sup>6</sup> Sample sizes do not correspond to RSD proportions because RSD proportions are weighted by abundance estimates in a stratified design.
